2.7. AC circuits & electromagnetic oscillations

How does a Tesla coil work? ew10

- electric resonant transformer circuit
- Tesla coil with primary and secondary winding, each forming its own LC-circuit
- spark gap (SG) acts as a switch
- need to understand: LRC-circuits, resonance,
 and impedance
- **plan for today**: investigate simply AC-circuits to derive deeper understanding of R, L, and C

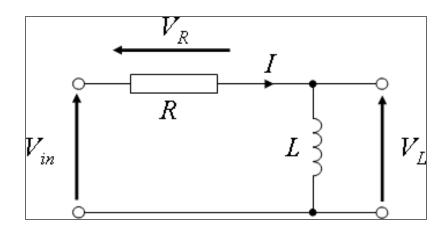

from wikipedia under CCO 1.0 Universal

LR-circuit

em45

- consider a simple DC circuit with the following elements in series:
 - lacktriangle ideal voltage source V_0
 - resistor *R*
 - lacktriangle inductor L

from <u>wikipedia</u> under <u>CC Attribution-ShareAlike 3.0</u> <u>Unported</u>

LR-circuit: Switching DC supply on

applying Kirchhoff's loop rule gives

$$V_0 = Lrac{dI}{dt} + IR$$

 rearrange and take integral (0..I and 0..t, i.e. current slowly builds up due to selfinductance):

$$\int_0^I \frac{dI}{V_0 - RI} = \int_0^t \frac{dt}{L}$$

solving the differential equation yields

$$I(t) = rac{V_0}{R} \Big(1 - e^{-tR/L} \Big)$$

LR-circuit: Switching DC supply on (cont')

• find V_L :

$$egin{align} V_L &= Lrac{dI}{dt} = rac{d}{dt} \left(rac{V_0}{R} \left(1 - e^{-tR/L}
ight)
ight) \ V_L &= L \Big(rac{V_0}{R} \cdot rac{-R}{L} \cdot e^{-tR/L}\Big) \ V_L &= -V_0 e^{-tR/L} \ \end{pmatrix}$$

- summary: self-inductance causes:
 - voltage over L to be first opposed to V_0 (Lenz's rule) and decaying over times
 - current building up over time

LR-circuit: Switching DC supply off

- when the DC supply is switched off ($V_0 = 0$) the inductor resists (again) change in current
- Kirchhoff's loop rule becomes

$$L\frac{dI}{dt} + IR = 0$$

solution for decaying current is:

$$I(t) = I_0 e^{-tR/L}$$

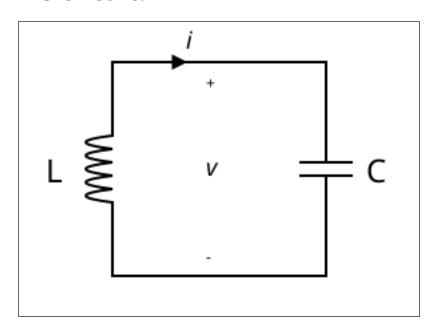

voltage over inductor is:

$$egin{aligned} V_L = Lrac{dI}{dt} &= rac{d}{dt}\Big(I_0e^{-tR/L}\Big) = rac{-LR}{L}I_0e^{-tR/L} \ V_L &= -V_0e^{-tR/L} \end{aligned}$$

LC-circuit: Fun with AC circuit

ew04

What happens if we put L and C in series in a AC circuit?

from <u>wikipedia</u> under <u>CC Attribution-ShareAlike 3.0</u> <u>Unported</u>

LC-circuit: The equations

applying Kirchhoff's rule leads to:

$$-L\frac{dI}{dt} + \frac{Q}{C} = 0$$

• using $I = -\frac{dQ}{dt}$ (minus because capacitor discharges)

$$\frac{d^2Q}{dt^2} + \frac{1}{LC}Q = 0$$

second order linear equation describing simple
 harmonic oscillator with general solution:

$$Q(t) = Q_0 \cos \Bigl(\omega t + \phi\Bigr) \quad ext{with the angular frequen}$$

• current I(t) is time derivative of charge:

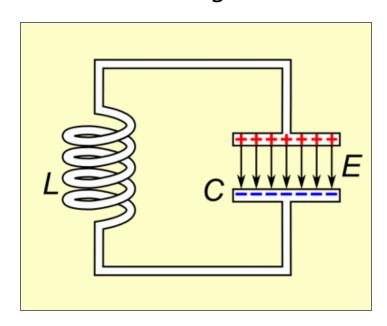

$$I(t) = -rac{dQ}{dt} = \omega Q_0 \sin(\omega t + \phi) = I_0 \sin(\omega t + \phi)$$

LC-circuit: Electromagnetic oscillations

 the energy oscillates between capacitor (electric field) and inductor (magnetic field):

$$U=U_B+U_E=rac{Q_0^2}{2C}{
m sin}^2(\omega t+\phi)+rac{Q_0^2}{2C}{
m cos}^2(\omega t+\phi)$$

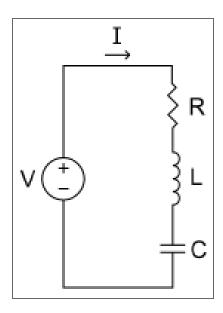

losses are neglected

from wikipedia under CCO 1.0 Universal

LRC-circuit

- adding a resistor
 - introduces damping into oscillations
 - models losses

from <u>wikipedia</u> under <u>CC Attribution-ShareAlike 3.0</u> <u>Unported</u>

LRC-circuit (cont')

sim - damping LRC-circuit

• apply Kirchhoff's loop rule and use $I=rac{dQ}{dt}$:

$$-L\frac{dI}{dt} - IR + \frac{Q}{C} = 0$$

$$Lrac{d^2Q}{dt^2}+Rrac{dQ}{dt}+rac{Q}{C}=0$$

- second-order linear differential equation that describes damped harmonic oscillator:
 - $R^2 < \frac{4L}{C}$: Underdamped oscillation with exponential decay
 - $R^2 > \frac{4L}{C}$: Overdamped, i.e. the damping is too strong to allow any oscillations
 - $R^2 = \frac{4L}{C}$: Critically damped oscillation with the angular frequency

$$\omega_d = \sqrt{rac{1}{LC} - rac{R^2}{4L^2}}$$

Resistance vs. reactance

ew01 - phase shift

- **LC-circuit**: energy conserved, only exchanged between L and C o oscillation o phase shift between V and I
- LRC-circuit: beyond oscillation, energy dissipated as heat in ${\cal R}$

• new concept:

- **resistance** *R* is independent of frequency and dissipates energy as heat
- **reactance** (inductive X_L and capacitive X_C) depends on frequency and temporarily stores energy
- the phase difference between voltage and current arises due to reactance

Resistor in AC circuit

- follows Ohm's law: V = IR
- ullet if current is sinusoidal, i.e. $I=I_0\cos(\omega t)$, the voltage is:

$$V = (I_0 \cos(\omega t))R = (I_0 R) \cos(\omega t) = V_0 \cos(\omega t)$$

- ullet o voltage and current are **in phase**
- the average power is given by

$$ar{P}=I_{rms}^2R$$

Inductor in AC circuit

• the voltage across an inductor is:

$$V-Lrac{dI}{dt}=0 \leftrightarrow V=Lrac{dI}{dt}$$

• for sinusoidal current $I(t) = I_0 \cos(\omega t)$, the voltage is:

$$V(t) = Lrac{d(I_0\cos(\omega t))}{dt} = -L\omega I_0\sin(\omega t)$$

• with $\sin(t) = -\cos(t + \frac{\pi}{2})$

$$V(t) = \omega L I_0 \cos\Bigl(\omega t + rac{\pi}{2}\Bigr) = X_L I_0 \cos\Bigl(\omega t + rac{\pi}{2}\Bigr)$$

- ullet the inductive reactance is $X_L=\omega L=2\pi f L$
- the voltage leads the current by 90°
- since X_L increases with frequency, inductors resist high-frequency currents more than low-frequency ones

Capacitor in AC circuit

ullet for a sinusoidal current $I(t)=I_0\cos(\omega t)=rac{dQ}{dt}$, charge at capacitor is:

$$Q(t) = \int_0^t dQ = \int_0^t I_0 \cos(\omega t) dt = rac{I_0}{\omega} \sin(\omega t)$$

• using $\sin\theta = \cos(\theta - \frac{\pi}{2})$, the voltage is:

$$V(t)=rac{Q}{C}=rac{1}{\omega C}I_0\sin(\omega t)=rac{I_0}{\omega C}\cos\Bigl(\omega t-rac{\pi}{2}\Bigr)=0$$

- the capacitive reactance is $X_C = \frac{1}{\omega C} = \frac{1}{2\pi f C}$
- the voltage lags the current by 90°
- since X_C decreases with frequency, capacitors resist low-frequency currents more than high-frequency ones

Summary of AC circuit components

- resistor:
 - no phase shift
 - dissipates energy as heat
- inductor:
 - voltage leads current
 - lacksquare reactance $X_L=\omega L$
- capacitor:
 - voltage lags current
 - reactance $X_C = \frac{1}{\omega C}$

Impedance

- impedance determines the relationship between voltage and current in AC circuits
- impedance combines resistance and reactance into a complex quantity:

$$Z=R+j\Bigl(X_L-X_C\Bigr)$$

- ullet its magnitude is $Z=\sqrt{R^2+\left(X_L-X_C
 ight)^2}$ and its phase angle is $an\phi=rac{X_L-X_C}{R}$
- ullet impedance in series: $Z_{net} = \sum_i Z_i$
- impedance in parallel: $\frac{1}{Z_{net}} = \sum_i \frac{1}{Z_i}$

Revisiting AC LRC-circuit: Phasor diagrams

sim - Phasor diagram

 in a series LRC-circuit the sum of the voltage drops equals the source voltage:

$$V = V_R + V_L + V_C$$

- in the phasor diagram:
 - V_R is drawn along the positive x-axis (in phase with the current)
 - V_L is drawn 90° ahead of V_R
 - V_C is drawn 90° behind V_R
- the resultant voltage is found by vector addition:

$$V_0 = I_0 Z \quad ext{with} \quad Z = \sqrt{R^2 + \left(X_L - X_C
ight)^2}$$

Impedance matching

el35 - CASSY

 maximum power transfer occurs when the source impedance matches the load impedance:

$$Z_1 = Z_2$$

- ullet for purely resistive circuits, maximum power is delivered when $R_{
 m source}=R_{
 m load}$
- mismatched impedances lead to reduced power transfer efficiency and potential signal distortion

Revisiting AC LRC-circuit: Resonance

sim - Resonance

- ullet resonance occurs when the inductive and capacitive reactances cancel: $X_L = X_C$
- the impedance is purely resistive:

$$Z=\sqrt{R^2+\left(X_L-X_C
ight)^2}=R$$

ullet o the resonant (angular) frequency is

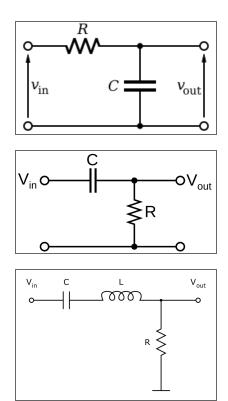

$$\omega_0 = \sqrt{rac{1}{LC}} \, \leftrightarrow \, f_0 = rac{1}{2\pi\sqrt{LC}}$$

- ullet ightarrow voltage and current are in phase: $\phi=0$
- ullet shape of resonance curve depends on the value of R

Filters

ew07 - high/low pass

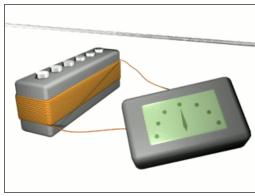

- low-pass filters allow low-frequency signals to pass while attenuating high-frequency ones
- high-pass filters allow high-frequency signals to pass while attenuating low-frequency ones
- band-pass filters allow frequency band to pass while attenuating frequencies below and above the band
- these filters are common in signal processing and audio electronics
